

I built an AI-assisted forensic engine that detects suspicious token-market behavior.

This first public case file is intentionally anonymized. It shows what Core Equity can prove today: coordination, circularity, tradability context, and why the system refuses to call it a client trade signal.

82

Behavior score

Strong anomaly

66.0%

Circularity

Wash-like flow

True

Sell observed

Not honeypot

False

Trade-ready

Safety gate

Forensic conclusion

Suspicious coordination was detected, but the economics did not support a safe long signal after friction. This is exactly why Core Equity separates forensic alerts from trading decisions.

1. Executive Summary

What the AI detected, and what it refused to do

- Case CE-001 is a BNB Chain token/pool investigation built from local raw Swap, Sync and Transfer context.
- The behavioral anomaly score reached 82/100 from repeatable exact swaps, dense timing, wallet concentration, transfers into pool and liquidity context.
- The engine did not require official protocol documentation to score behavior. Identity proof remains separate for mapping or client-facing actions.
- The outcome/backtest layer rejected the long-style trade thesis: no positive shadow edge after conservative frictions.
- Final status: forensic-only case file, useful for research, compliance, listing-risk and fake-volume screening; not a trade signal.

Plain-English verdict

The model saw a coordinated crowd. Then it checked whether that crowd created a tradable opportunity. It did not. This matters: the system protected the user from confusing suspicious activity with profitable activity.

2. Evidence Inventory

Raw signals used in the case file

50

Raw swaps

Exact local swap events

50

Sync events

Liquidity/reserve context

37

Transfers

Token movement context

32

Unique txs

Repeatability check

32

Unique blocks

Not one isolated tick

23

Unique wallets

Participant breadth

Evidence discipline

- Every row is treated as research evidence, not as an execution command.
- Official identity is separated from behavioral scoring: unknown identity does not block forensic analysis, but it still blocks mapping/signals/trades.
- The report uses anonymized identifiers for publication safety.

3. Funder / Participant Graph

Graph context from local wallet and transaction evidence

Graph reading

- Funder graph status: needs_funder_graph_collection
- Fresh-like wallets observed: 3 / wallet states available: 3
- Interpretation: strong behavioral evidence exists, but the funding graph is not complete enough for identity attribution.

4. Coordination Timeline

Dense behavior, fast threshold crossing

Observed swap span: 2.9167 minutes. Max swaps in 5m/20 blocks: 50.

The timeline is the key lesson: the detector correctly found abnormal coordination, but even earlier thresholds did not create a profitable post-friction edge.

5. Circularity / Wash-Trading Evidence

Why activity did not equal alpha

66.0%

Circularity ratio

high_circularity

16

Buy flows

Target buys

34

Sell flows

Target sells

Interpretation

- High circularity suggests repeated internal flow or wash-like volume rather than clean directional accumulation.
- Hold/freeze proxy: 44.2572%, which is not enough to classify the case as alpha-ready accumulation.
- AMM impact vs volume: 21.8212%, so some reserve impact exists, but not enough to override the circularity risk.

6. Outcome / Backtest Economics

The system refuses weak economics

0.25%

Best raw MFE

Before friction

-9.75%

After friction

Slippage/MEV/tax buffer

28

Sell checks

Third-party sells observed

Why this matters

- The token appears tradable: post-T0 sells were observed, so the case is not a simple honeypot wall.
- But the opportunity was economically bad after friction. Suspicious behavior did not become a safe long signal.
- This is the product moat: Core Equity does not confuse forensic detection with a client trade recommendation.

7. Safety Gates

What remains blocked by design

No client signal

No trade

No mapping

No label

No opt-in

No accusation

Blocked because

- Source identity is separate from behavior: behavior can be scored, but it cannot become a mapping or public label without stronger evidence.
- Backtest economics are negative after friction: no client-facing alpha claim.
- Funder graph is not complete enough for attribution: no public naming or accusation.
- This case is valuable as a fake-volume / wash-trading / market-abuse risk case file, not as a trade.

8. Product Value

Why this can become more valuable than a trading bot

Possible customers

- Crypto funds: avoid fake-volume traps before entering positions.
- Listing/research teams: flag tokens with suspicious circular flow.
- Forensic analysts: prioritize wallet clusters and funding graph investigations.
- Market-data products: offer a manipulation-risk API instead of generic price alerts.

API angle

A public case file does not need to reveal every internal heuristic. It should prove that the engine can separate: suspicious behavior, fake-volume risk, economic exploitability, and safe/no-safe action gates.

9. Conclusion

First public proof-of-capability

Case CE-001 conclusion

Core Equity detected a strong behavioral anomaly, identified high circularity, verified that selling was possible, tested earlier entry thresholds, and still refused to produce a trade signal because the economics failed after friction.

Public framing

This is the right first case to publish because it is not hype. It shows discipline. The AI did not say 'buy'. It said: 'this is suspicious, here is why, and here is why it is not safe to trade.'

Suggested next public artifact

- Publish the anonymized thread first.
- Offer the full PDF by DM to serious funds/researchers.
- Do not tag people aggressively on the first post; tag lightly or reply with the PDF after interest appears.
